# INTERACTIVE GRAPHICS PLOTTING SYSTEM (IGPS)

## 1. INTRODUCTION

IGPS (Interactive Graphics Plotting System) is a computer-graphics program, written in BASIC for the Tektronix 4051 desktop computer, which generates high-quality plots of two-dimensional data; the plots can be used for slide presentations or can be inserted into reports.

The program is interactive and prompts the user for all the information required to construct a plot; furthermore, the program is structured to permit rapid changes to an existing plot. Therefore, the user can keep modifying the plot he is drawing and can preview it on the screen of the Tektronix 4051 until he is satisfied with its appearance. Then, simply by depressing one key on the keyboard, the user can exactly reproduce his plot on a Tektronix 4662 x-y plotter.

Figure 1.1 is a sample plot produced in this fashion by IGPS on a 4662. The plot was drawn directly onto a piece of report paper 8-1/2 inches high by 11 inches long placed in the lower left-hand corner of the 4662. The figure number, title, and page number were then added with a conventional typewriter.

The sample, which could have been used directly to make a slide, displays some of the features of IGPS: an unusual axis system (in fact, Rayleigh Paper), neat tick mark and axis labeling, multiple curve marker types, legends, and curve fitting. Table 1-1 is a summary of the features currently available with IGPS.

# ACCURACY OF CROSSBOWS

Figure 1.1 Sample Plot Produced by IGPS

TABLE 1-1 SUMMARY OF IGPS

---

Tick Mark Spacing:

- uniform
- user-controlled

Tick Mark Labeling:

- uniform with automatic decimal-point selection
- user-controlled

Frame Types:

- axis
- grid
- border
- suppressed

Standard Paper Types:

- linear in x and y
- linear in x, logarithmic in y
- logarithmic in x, linear in y
- logarithmic in x, logarithmic in y
- user-definable

Probability Paper Types:

- uniform distribution
- normal distribution
- lognormal distribution
- Rayleigh distribution
- Weibull distribution
- user-defined distribution

Input/Output Devices:

- Tektronix 4051 Internal Tape Drive
- Tektronix 4924 Auxiliary Tape Drive
- Tektronix 4907 File Manager (Disc)

Line Types:

- solid
  - dashed
  - dashed-dotted
  - dotted
-

TABLE 1-1 SUMMARY OF IGPS (continued)

---

Curve Markers:

- crosses
- x-shaped
- squares
- triangles
- upside-down triangles

Curve Fits (Linear, Least-Squares):

- estimate slope and intercept
- estimate slope, intercept fixed
- estimate intercept, slope fixed

Plotting Devices:

- Tektronix 4051 Screen
  - Tektronix 4662
  - Tektronix 4662, Option 31
-

## 2. USING IGPS

Once IGPS has been loaded into the memory of the Tektronix 4051, it needs to be initialized. This can be done by typing in RUN followed by a carriage return. IGPS will initialize itself and will display the following menu on the screen of the 4051.

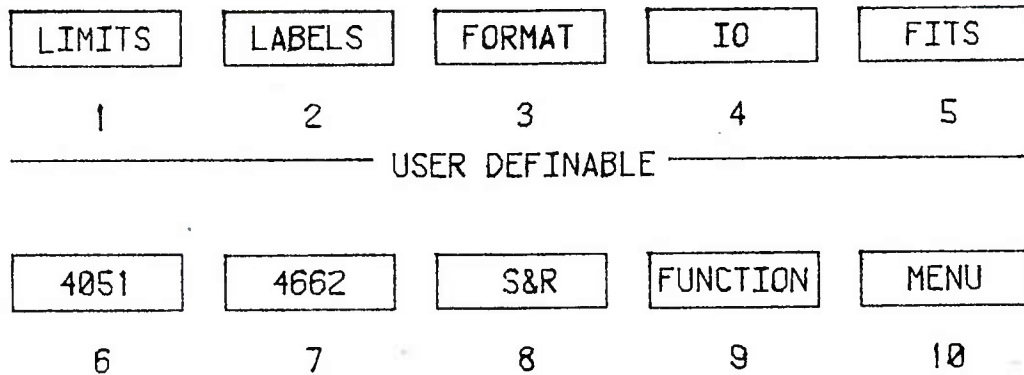

Figure 2.1 Menu for IGPS

The 10 rectangles in the menu correspond to the 10 user-definable keys located in the upper left-hand corner of the keyboard of the 4051. These 10 keys are used to control IGPS.

If, at any time during a plotting session with IGPS, the user wishes to examine the menu, he can either type in RUN followed by a carriage return or he can depress user key number 10.

Table 2-1 summarizes the action of the 10 user-definable keys.

TABLE 2-1 SUMMARY OF USER KEYS

<u>User Key Number</u>	<u>Function</u>
1	Establish limits over which plotting is done.
2	Inputs axis labels and title.
3	Defines axis system.
4	Inputs data curves from peripheral or keyboard; saves data curves on peripheral.
5	Does least-squares, linear fits on data curves.
6	Plots graph on screen of 4051.
7	Plots graph on 4662 x-y plotter.
8	Stores graph on peripheral; retrieves previously saved graph from peripheral.
9	Generates x-y data from user-defined parametric functions.
10	Displays menu on the screen.

### 2.1 User Key Number 1: Limits.

This key is used to establish the limits between which data plotting is to take place (in other words, data outside the limits will not be plotted); the key is also used to define the distance between tick marks and between tick mark labels.

After the user depresses key number 1, IGPS will prompt him with

UNIFORM TICKS ON THE X AXIS (1=YES, 2=NO):

If the user responds with a 1, meaning that he wants uniformly spaced tick marks and labels, IGPS will prompt with

XMIN:  
XMAX:  
MAJOR TICKS:  
MINOR TICKS:

The user should respond to each prompt with a suitable number. The response to XMIN establishes the smallest value on the x axis and that to XMAX the largest. The response to MAJOR TICKS establishes the distance between adjacent tick mark labels and the response to MINOR TICKS the distance between adjacent tick marks. The sequence to generate the x axis of Figure 1.1, for instance, is

XMIN: 0  
XMAX: 96  
MAJOR TICKS: 12  
MINOR TICKS: 4

In no case should XMIN ever be the same as XMAX and, for best results, MAJOR TICKS and MINOR TICKS should be multiples of the difference between XMAX and XMIN; furthermore, MAJOR TICKS should be a multiple of MINOR TICKS. Results are unpredictable if these conditions are not met. In fact, IGPS will create  $n$  tick marks, where

$$n = 1 + [(XMAX - XMIN) / MINOR TICKS] ,$$

and the quantity in brackets denotes "the largest integer not to exceed," and the tick marks will appear at points  $x_i$  such that

$$x_i = XMIN + MINOR TICKS \cdot (i-1), i=1, \dots, n.$$

Similarly, IGPS will create  $m$  tick mark labels, where

$$m = 1 + [(XMAX - XMIN) / MAJOR TICKS] ,$$

and the labels will appear at points  $l_i$  such that

$$l_i = XMIN + MAJOR TICKS \cdot (i-1), i=1, \dots, m.$$

Clearly, if MAJOR TICKS is the same as MINOR TICKS, then all tick marks will be labeled.

Consider the sequence

XMIN: 0  
XMAX: 1  
MAJOR TICKS: 0.25  
MINOR TICKS: 0.25

This produces the following x axis

Figure 2.2 Sample Axis with Uniform Tick Marks and Labels

Note that the labels are drawn centered under the appropriate tick mark, and that all labels have the same number of digits (two) to the right of the decimal point. Note also that two digits beyond the decimal point is the ideal number in this situation, in the sense that using any fewer would have caused a loss of accuracy while using any more would have caused unnecessary trailing zeroes. IGPS calculates and uses this ideal number automatically.

If the user does not like uniformly spaced tick marks and tick mark labels with automatic decimal-point selection on the x axis, then he should respond with a 2 to the prompt

UNIFORM TICKS ON THE X AXIS (1=YES, 2=NO):

By doing so, he assumes total control over the placement and appearance of tick marks and labels; after such a response, IGPS prompts with

NUMBER OF TICK MARKS (AT LEAST 2):

LOCATION OF TICK MARKS:

NUMBER OF TICK MARK LABELS:

LOCATION OF TICK MARK LABELS:

The meaning of these prompts is obvious.

At least two tick marks are required since the first one entered is assumed to be the minimum value along the x axis while the last one is assumed to be the maximum value. The number of tick mark labels, however, is unrestricted and may even be zero; if it is zero, the fourth prompt is not displayed since it is not needed.

The locations of tick mark labels must all be entered on one line and must be separated by a single blank or by a comma. The labels will be plotted by IGPS exactly as they were entered (in other words, IGPS will not calculate the number of places beyond the decimal point for the labels but will use as many as the user himself typed in).

For example, the sequence

```
NUMBER OF TICK MARKS (AT LEAST 2): 19
LOCATION OF TICK MARKS:  .1  .2  .3  .4  .5  .6  .7  .8  .9
                      1   2   3   4   5   6   7   8   9
                      10
NUMBER OF TICK MARK LABELS: 3
LOCATION OF TICK MARK LABELS: .1 1 10
```

if used in conjunction with a logarithmic x axis, will produce

Figure 2.3 Sample Axis with User-Controlled Tick Marks and Labels

Once the user has supplied the specifications for the x axis, IGPS will prompt for the y axis in exactly the same way as it did for the x axis.

## 2.2 User Key Number 2: Labels.

This key is used to establish the axis labels and the title of the plot. If the user does not want these items, he should respond with a carriage return when prompted for them.

The x-axis label is plotted below the plotting area and is centered between the x-axis limits. The title of the plot is similarly centered but is plotted above the plotting area and is underlined twice (if the plot has no title, no underlining takes place). The y-axis label is plotted to the left of the plotting area and is centered between the y-axis limits. When plotted on the 4662 x-y plotter, the y-axis label will be written along a baseline rotated 90 degrees from the horizontal (see Figure 1.1); on the screen of the 4051, however, the individual characters are plotted on the horizontal, with the first character above the second, the second above the third, and so on (as in Chinese or Japanese)--this is done because the character-generator of the 4051 cannot produce rotated characters. Close examination of Figure 1.1 will reveal that different character sizes are used in various parts of the plot; this feature is also only available on the 4662 because the character-generator of the 4662 can produce characters of arbitrary size, unlike the generator of the 4051.

## 2.3 User Key Number 3: Format.

This key is used to control the basic appearance of the graph: it determines the type of frame which will be used, the speed at which the graph will be drawn, the color of the frame

and labels and, more importantly, the type of paper which will be used.

After the user depresses user key number 3, IGPS will ask for the type of frame the user wants. There are four possible answers: zero, meaning no frame or labels are to be drawn; one, meaning draw an axis system; two, meaning draw a grid; and three, meaning draw borders.

The first option is useful when a set of curves is to be added to a graph because it avoids re-plotting most of the graph.

The second option produces axes running along the left-hand side and the bottom of the plotting area.

Figure 2.4 Sample Axis System

The third option produces a grid over the plotting area; each tick mark is indicated with a solid line.

Figure 2.5 Sample Grid

The fourth option produces axes and tick marks along the edges of the plotting area.

Figure 2.5 Sample Borders

After he selects a frame type, the user will be prompted for the color of the frame and labels. He must reply with an integer between one and eight, corresponding to the eight pens in the turret of the 4662 x-y plotter equipped with Option 31. The choice of color is ignored if plotting is either on the screen of the 4051 or on a standard 4662.

The user is then asked for a pen speed, to which he must respond with an integer between 10 and 570. The answer is interpreted in millimeters per second and is the maximum speed at which the 4662, Option 31, plotter will draw (the response is ignored on the 4051 or the standard 4662). For previewing, the user should select 570 mm/s. However, for best results, he should select 10 mm/s since the lower speed leads to much sharper definition of vectors.

The final prompt associated with user key number 3 is for the type of paper the user wants. IGPS will display

PAPER TYPES:		X-AXIS	Y-AXIS
1.	LINEAR:	X	Y
2.	XLOG:	LOG(X)	Y
3.	YLOG:	X	LOG(Y)
4.	LOGLOG:	LOG(X)	LOG(Y)
5.	USER:	?	?
6.	UNIFORM:	X/100	Y
7.	NORMAL:	N(X/100)	Y
8.	LOGNORMAL:	N(X/100)	LOG(Y)
9.	RAYLEIGH:	$\text{SQR}(-2*\text{LOG}(1-X/100))$	Y
10.	WEIBULL:	$\text{LOG}(-\text{LOG}(1-X/100))$	LOG(Y)

PAPER TYPE:

to which the user should respond with an integer between one and 10, corresponding to his choice of paper. As indicated by the prompt, the user's choice is in fact a selection of two transformations, or functions, one function for the x axis and one for the y axis. All data, including tick mark locations (but not tick mark labels) related to the x coordinate are transformed via the x-axis function before being plotted, as are all data related to the y coordinate via the y-axis function. Since the reader may not be familiar with all available paper types, we will describe each one, with its associated functions, separately.

2.3a Linear Paper. This is the most commonly used type of paper and is in fact plain graph paper. The two functions associated with this paper are the identity functions and therefore have no effect.

Figure 2.6 Example of the use of Linear Paper.

2.3b Xlog Paper. This paper has a logarithmic x axis and a linear y axis; therefore, all x-axis data are transformed via the function

$$F_a(x) = \ln x$$

before being plotted. Because of this transformation, there are implications for the meaning of the slope and intercept of any straight line which the user might choose to fit to his data while using xlog paper (Section 2.5, User Key Number 5). In particular, if we let  $a$  be the slope of such a line and if we let  $b$  be its intercept, and if the line appears to fit the user's data plotted on xlog paper, then an appropriate model of the user's data is:

$$y = a \ln x + b .$$

Though this may be perfectly obvious in this case, we have chosen to emphasize the point here because the situation becomes much more complex with other types of paper (transformations). In general, if we denote the two axis transformations by  $F_a(x)$  and  $F_b(y)$ , then any straight line used with those transformations is in fact a model of the form:

$$F_b(y) = a F_a(x) + b .$$

If the user wants the model in simpler form, with only the  $y$  term appearing to the left of the equal sign, he will have to apply the inverse of  $F_b$  to both sides of the equation; this point is illustrated explicitly in the next section.

2.3c Ylog Paper. This paper has a linear  $x$  axis and a logarithmic  $y$  axis. To illustrate the use of this paper, consider the data in Table 2-2.

TABLE 2-2 VALUES OF AIR DENSITY AS A FUNCTION OF ALTITUDE

Altitude (km)	0	1	2	3	4	5	6
Air Density (kg/m <sup>3</sup> )	1.22	1.11	1.01	0.91	0.82	0.74	0.66
Altitude (km)	7	8	9	10	11	12	13
Air Density (kg/m <sup>3</sup> )	0.59	0.53	0.47	0.41	0.36	0.31	0.27
Altitude (km)	14	15	16	17	18	19	20
Air Density (kg/m <sup>3</sup> )	0.23	0.19	0.17	0.14	0.12	0.10	0.09

From physical reasoning, or for some other reason, we decide that air density is an exponential function of altitude (in other words, that the logarithm of air density is a linear function of altitude). To test this hypothesis, we plot the data on ylog paper and fit a straight line with user key number 5.

Figure 2.7 Example of the Use of Ylog Paper

The plot confirms our hypothesis. The slope and intercept of the line calculated by IGPS are:

$$\begin{aligned} a &= -0.13, \\ \text{and} \\ b &= 0.34. \end{aligned}$$

Therefore, our model of air density ( $p$ ) versus altitude ( $h$ ) is:

$$\begin{aligned} \ln p &= -0.13 h + 0.34, \\ \text{or} \end{aligned}$$

$$p = 1.40 e^{-0.13h}.$$

Note that this model does not go through the data point at zero altitude. Suppose we should want it to, in other words, suppose we should like a model of the form:

$$p = 1.22 e^{-kh}.$$

what is the best value of  $k$  (in the least-squares sense)? Taking logarithms produces:

$$\ln p = -kh + 0.20.$$

To determine k, we depress user key number 5 and request a straight-line fit with a forced intercept of

$$b = 0.20 .$$

IGPS will calculate the slope of that line as:

$$a = -0.12$$

It is clear, therefore, that the value of k we are looking for is:

$$k = 0.12 ,$$

and that the best model which goes through the value of air density at zero altitude is:

$$p = 1.22 e^{-0.12h} .$$

2.3d Loglog Paper. This paper has a logarithmic x axis and a logarithmic y axis. Therefore, straight-line fits to data plotted on this paper are models of the form:

$$\ln y = a \ln x + b .$$

The user is cautioned that whenever he is using a logarithmic axis, be it horizontal or vertical, he must avoid zero or negative values along that axis, both in the data being plotted and in the choice of tick marks. This is because the logarithm of a non-positive number is undefined.

2.3e User-Definable Paper. This is one of the most powerful features of IGPS because it allows the user to define his own transformations for the axes and therefore provides an unlimited supply of paper types. If you want to use this feature, you must define your transformations before you depress user key number 3 and you must then select user-definable paper.

To define your transformations, you must replace lines 4590 and 4600 in the program with your own functions. The transformation for the x axis must appear on line 4590 and must be of the form

```
4590 DEF FNA(X)=
```

where you supply the information to the right of the equal sign. Line 4600 is for the y axis and must be of a similar form

```
4600 DEF FNB(Y)=
```

To illustrate the power of this feature, consider the data appearing in Table 2.3.

TABLE 2-3 SAMPLE DATA

x	3.00	2.70	2.30	1.80	1.60	1.27	1.10
y	.225	.241	.267	.304	.321	.351	.365

Plotting the data on ordinary, linear, graph paper reveals nothing unusual about them.

Figure 2.8 Sample Data Plotted on Linear Paper

Incidentally, the source of the data and the units associated with them do not concern us here. What does concern us is that a model of the form

$$y = \frac{k}{\sqrt{x}}$$

has been suggested for the data. To test this model, we type in

```
4590 DEF FNA(X)=-1/SQR(X)
```

```
4600 DEF FNB(Y)=Y
```

we select user-definable paper and we ask for a curve fit with a forced intercept of b=0.

Figure 2.9 Sample Data Plotted on User-Defined Paper

IGPS calculates the slope of the line as  $a = -0.40$ . This means that one possible model of the data is:

$$y = \frac{0.40}{\sqrt{x}}$$

Note that the x axis on user-definable paper starts at 1, whereas the x axis on ordinary paper starts at zero. This difference is necessary because the transformation of zero on user-definable paper would lead to an undefined number (in other words,

$$\frac{-1}{\sqrt{0}} = \infty).$$

Note also that we defined the x-axis trans-

formation as

$$F_a(x) = -\frac{1}{\sqrt{x}}, \text{ rather than as}$$

$$F_a(x) = \frac{1}{\sqrt{x}}.$$

The minus sign is required to make the transformed value of the minimum along the x axis smaller than the transformed value of the maximum (in other words, if the minus sign had not been included, we would have had  $F_a(1) > F_a(4)$ , which is not allowed

on the Tektronix). The minus sign has to be taken into account when interpreting the results of the curve fitting (which was done in constructing the final model above).

The final point to make about this example is that the value of the free parameter in our model could have been read directly off the graph at the point where the fitted line intersects the vertical line  $x=1$ . One way to see this is to note that, in our model,  $y=k$  when  $x=1$ .

What this example has illustrated is that user-definable paper, in conjunction with curve-fitting, can be used to test the adequacy of a large class of models in representing given data (though no mention of this has yet been made, it will be shown in Section 2.5 that IGPS, when curve-fitting, generates a quantitative estimate of the goodness-of-fit of the model; this estimate is known as  $R^2$ ). As another example, consider the data in Table 2-4.

TABLE 2-4 MORE SAMPLE DATA

x	1	2	3	4
y	1.01	2.28	3.92	6.13

One proposed model for these data is:

$$y = \frac{x}{1.1 - kx} .$$

By inverting both sides of the equation and multiplying by  $-1$ , this model can be transformed into:

$$-\frac{1}{y} = -\frac{1.1}{x} + k .$$

Therefore, we can check the adequacy of the original model by typing

```
4590 DEF FNA(X)=-1/X
4600 DEF FNB(Y)=-1/Y
```

and then selecting user-defined paper and doing a curve fit with a forced slope of  $a = 1.1$ .

Figure 2.10 Another Example of User-Defined Paper

The plot shows that the model is a good one and as IGPS calculates the intercept of the line as  $b = 0.11$ , we know the value of the free parameter  $k$ . Therefore our model becomes:

$$y = \frac{x}{1.1 - 0.11x} .$$

This example illustrates that a particular model may need to be manipulated before it can be used to define a paper type. In general, to define a paper type, a model will have to be put into the form:

$$F_b(y) = a F_a(x) + b ,$$

where  $F_a$  and  $F_b$  are functions of  $x$  and  $y$  and where  $a$  and  $b$  are functions of the free parameters of the original model.

The paper types described so far have been suitable for sets of two-dimensional,  $x$ -versus- $y$ , data. We now describe several types of paper suitable for testing whether a set of data is from a particular probability distribution.

2.3f Uniform Probability Paper. Let us imagine that we have a sample of  $n$  points,  $d_i$ ,  $i=1, \dots, n$ , from a uniform distribution on the interval  $(A, B)$ . Suppose further that the cumulative fraction of the data associated with the  $i^{\text{th}}$  point is  $q_i$ ,  $i=1, \dots, n$ . The  $q_i$ 's can be determined in two steps: (1) sort the  $d_i$ 's into increasing order and (2) calculate  $q_i$  as:

$$q_i = \frac{i}{1 + n}, \quad i=1, \dots, n.$$

Since the  $d_i$ 's are uniformly distributed, it must be the case that

$$q_i = F(d_i), \quad i=1, \dots, n,$$

where  $F$  is the cumulative distribution function (c.d.f.) of the uniform distribution on  $(A, B)$ :

$$q = F(x) = \begin{cases} 0, & x < A, \\ \frac{x - A}{B - A}, & A \leq x \leq B, \text{ and} \\ 1, & x > B. \end{cases}$$

It follows, therefore, that

$$d_i = F^{-1}(q_i), \quad i=1, \dots, n,$$

where  $F^{-1}$  represents the inverse of  $F$  (the existence of  $F^{-1}$  can be guaranteed by restricting the domain of  $F$  to the interval  $A \leq x \leq B$ ). In other words,

$$d_i = (B-A) q_i + A, \quad i=1, \dots, n,$$

so that if we plot the  $d_i$ 's against the  $q_i$ 's, we should be able to fit a straight line to the plotted points; what is more, if the slope of the line is  $a$  and its intercept is  $b$ , we can calculate the parameters of the distribution from  $a = B - A$  and  $b = A$ ; these two equations in fact imply  $A = b$  and  $B = a + b$ .

Consider the data in Table 2-5.

TABLE 2-5 UNIFORM NUMBERS

5.39	5.87	6.41	5.00
6.76	6.01	6.62	5.64
5.41	6.28	6.87	5.65
5.81	6.50	5.17	6.41
6.83	6.74	5.22	5.16

To check the uniformity of the data, we sort them in increasing order, generate the associated cumulative fractions, and plot them after asking for a curve fit (IGPS will, if requested, do the sorting and the generating of cumulative fractions; note that the fractions are expressed as percentages, however). The plot provides convincing evidence of the uniformity of the numbers; furthermore, the curve fit produces a slope  $a = 2.24$  and an intercept  $b = 4.87$ . We conclude that the numbers are from a uniform distribution on  $(4.87, 7.11)$ .

Figure 2.11 Example of the Use of Uniform Probability Paper

2.3g Normal Probability Paper. This paper can be used to check if a given sample of data is from a normal, or gaussian, distribution.

Imagine that we have a sample of  $n$  points  $d_i$ ,  $i=1, \dots, n$ , from a normal distribution with unknown parameters  $m$  and  $s$ . We can transform the  $d_i$ 's to standard form by setting

$$z_i = \frac{d_i - m}{s}, \quad i=1, \dots, n.$$

Furthermore, since the  $d_i$ 's are normally distributed, then the  $z_i$ 's are distributed according to the standard normal distribution, and it must therefore be the case that

$$q_i = F(z_i), \quad i=1, \dots, n,$$

where the  $q_i$ 's are the cumulative fractions of the data and  $F$  is the c.d.f. of the standard normal distribution:

$$F(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-1/2 t^2} dt.$$

It follows that

$$z_i = F^{-1}(q_i), \quad i=1, \dots, n,$$

and from the definition of  $z_i$  we have

$$\frac{d_i - m}{s} = F^{-1}(q_i), \quad i=1, \dots, n$$

or

$$d_i = s F^{-1}(q_i) + m, \quad i=1, \dots, n.$$

Therefore, if we plot  $d_i$  against  $F^{-1}(q_i)$ ,  $i=1, \dots, n$ , the result will approximate a straight line whose slope and intercept can be used directly to estimate  $m$  and  $s$ . Consider the data in Table 2-6.

TABLE 2-6 NORMALLY DISTRIBUTED DATA (FREQUENCY)

Frequency	.12	.22	.29	.18	.15	.02
Value	3.0	3.5	4.0	4.5	5.0	5.5

The same data, in cumulative form, appears in Table 2-7.

TABLE 2-7 NORMALLY DISTRIBUTED DATA (CUMULATIVE)

Cumulative Frequency (%)	12	34	63	81	96	98
Value	3.0	3.5	4.0	4.5	5.0	5.5

We enter the data in Table 2-7 into IGPS after selecting normal paper and we do a curve fit.

Figure 2.12 Example of the Use of Normal Probability Paper

Estimates of the mean and standard deviation provided by the curve fitting are  $m = 3.82$  and  $s = 0.75$ . These two quantities can also be estimated from the graph: the mean is the point at which the line intersects the 50<sup>th</sup> percentile while the standard deviation is the difference between this value and the value

corresponding to a cumulative fraction of 0.8413. These assertions can be verified as follows: our model is of the form

$$d = sF^{-1}(q) + m ,$$

and therefore  $d = m$  where  $F^{-1}(q) = 0$  and  $F^{-1}(q) = 0$  when  $q = 0.50$ . To find  $s$ , note that  $s = d - m$  when  $F^{-1}(q)=1$  and this is true when  $q = 0.8413$ . Another way to see this is to note that the mean and median of the standard normal distribution are equal while one standard deviation about the mean spans 68.26 percent of the distribution (and 50 percent plus one-half of 68.26 percent equals 84.13 percent).

Note that the x-axis tick mark labels on the graph avoid the values zero and 100. This should always be done when using normal paper because  $F^{-1}(0) = -\infty$  and  $F^{-1}(1) = +\infty$ .

Finally, a remark about  $F^{-1}$  itself: since  $F^{-1}$  cannot be expressed in closed form (that is to say in terms of sums and products of functions available on the Tektronix 4051), IGPS uses an approximation of  $F^{-1}$  due to Hastings (reference 1, page 192).

The approximation is:

$$F^{-1}(q) = \begin{cases} G(1-q) , & q > .5 , \\ -G(q) , & q \leq .5 , \end{cases} \quad \text{and}$$

where

$$G(q) = z - \frac{h(z)}{s(z)} ,$$

$$z = \ln \frac{1}{q^2} ,$$

$$h(z) = 2.515517 + 0.802853 z + 0.010328 z^2 , \text{ and}$$

$$s(z) = 1 + 1.432788 z + 0.189269 z^2 + 0.001308 z^3.$$

It is claimed that the error made in using the approximation is never greater than 0.0004 standard deviations.

2.3h Lognormal Probability Paper. Lognormal paper is similar to normal paper in all respects save one: the y axis of lognormal paper is logarithmic whereas the y axis of normal paper is linear. Therefore, lognormal paper can be used to test whether a sample of data is from a lognormal distribution, that is to say, that the logarithm of the sample is normally distributed.

2.3i Rayleigh Probability Paper. The Rayleigh distribution has c.d.f.

$$q = F(d) = 1 - e^{-\frac{1}{2} \left(\frac{d}{s}\right)^2}.$$

This can be readily transformed into

$$d = s \sqrt{-2 \ln (1 - q)}.$$

Therefore, given a sample of  $n$  points  $d_i$ ,  $i=1, \dots, n$ , with cumulative fractions  $q_i$ ,  $i=1, \dots, n$  we can test whether the sample is from a Rayleigh distribution by plotting  $d_i$  against  $\sqrt{-2 \ln (1 - q_i)}$ ,  $i=1, \dots, n$ . Furthermore, we can estimate  $s$  by fitting a line with intercept  $b = 0$  and slope  $a$  to the transformed data and setting  $s = a$ . The data in Table 2-8 will illustrate the procedure.

TABLE 2-8 NUMBERS FROM A RAYLEIGH DISTRIBUTION

320	470	16	619
356	547	264	204
429	703	265	305
501	128	468	662
608	143	121	524

We input the data to IGPS, ask IGPS to sort it and generate the cumulative fractions, ask IGPS for a curve fit with a forced intercept of  $b=0$ , and plot the results on Rayleigh paper.

Figure 2.13 Example of the use of Rayleigh Probability Paper

One estimate of the parameter  $s$  is provided by the curve fit as  $s = 314$ . Another is provided directly from the graph at the point where the line intersects the 39<sup>th</sup> percentile. This is the case because our model is:

$$d = s \sqrt{-2 \ln(1-q)} ,$$

and therefore  $d = s$  when  $\sqrt{-2 \ln(1-q)} = 1$ , which is the case when  $q = 39\%$ .

Note that the value 100 is not used as an x-axis tick mark label; this is because when  $q = 1$ ,  $\sqrt{-2 \ln(1-q)} = +\infty$ .

2.3j Weibull Probability Paper. The Weibull distribution has c.d.f.

$$q = F(d) = 1 - e^{-kd^c}, \quad d > 0, \quad k > 0.$$

This can be transformed, by taking logarithms twice, into

$$\ln d = \frac{1}{c} \ln [-\ln(1-q)] - \frac{1}{c} \ln k.$$

Weibull paper is ruled according to the function

$$F_a(x) = \ln [-\ln(1-x)]$$

along the x axis and according to the function

$$F_b(y) = \ln y$$

along the y axis. Therefore, given a set of data  $d_i$ ,  $i=1, \dots, n$ , from a Weibull distribution with parameters  $c$  and  $k$ , with associated cumulative fractions  $q_i$ ,  $i=1, \dots, n$ , then, if we plot  $d_i$  against  $q_i$ ,  $i=1, \dots, n$ , on Weibull paper, the result should approximate a straight line. Furthermore, if the slope of the line is  $a$  and its intercept is  $b$ , then estimates of  $c$  and  $k$  are given by

$$c = \frac{1}{a} , \quad \text{and}$$

$$k = e^{-b/a}$$

Note that, because of the definition of  $F_a$ , values of zero and 100 should be avoided on the x-axis (in fact,  $F_a(0) = -\infty$  and  $F_a(1) = +\infty$ ); similarly, non-positive values should not be used along the y axis.

Before leaving this section, we should point out that the user can define his own probability paper by using the ideas developed in Section 2.3e. For instance, suppose the user is interested in constructing paper for the exponential distribution. Now the exponential distribution has c.d.f.

$$q = F(d) = 1 - e^{-cd}, \quad c > 0.$$

By rearranging and taking logarithms, this can be converted to

$$d = - \frac{1}{c} \ln (1 - q) .$$

Therefore, to construct exponential paper, the user would type in:

```
4590 DEF FNA(X)=-LOG(1-X/100)
```

```
4600 DEF FNB(Y)=Y
```

and would then select user-definable paper. Note that the argument of the function FNA is divided by 100; this is done to allow the x-axis tick marks and labels to be expressed as percentages.

We leave to the reader the problem of determining what kind of curve fit to use with exponential paper and how to estimate the parameter  $c$  from the results of the curve fit.

The overall strategy for creating distribution paper, however, is clear: the c.d.f. of the distribution of interest is manipulated into the form

$$F_b(d) = a F_a(q) + b,$$

where  $F_a$  and  $F_b$  are functions of the cumulative frequency of the data and of the data itself and  $a$  and  $b$  are functions of the free parameters of the distribution.

#### 2.4 User Key Number 4: Input and Output.

This key is used either to input data curves into IGPS or to save previously entered curves from IGPS onto a Tektronix peripheral.

2.4a Input. After the user chooses to input data into IGPS, he will be prompted with

```
DATA TYPE (1 = Y ONLY, 2 = X & Y) :
```

A response of 1 indicates that the user is only going to input y-coordinate data whereas a response of 2 indicates that he is going to input both x-axis and y-axis data. A response of 1 is also a request to IGPS to do two things: (1) sort the y-axis data in increasing order and (2) generate x-axis data as:

$$x_{i,j} = 100 \frac{j}{1 + m_i}, \quad j = 1, \dots, m_i, \quad i = 1, \dots, n,$$

where  $n$  is the number of curves in the data set and  $m_i$  is the number of points in the  $i^{\text{th}}$  curve. This feature is useful with probability paper; see sections 2.3f through 2.3j.

The user is then prompted for the device he wants to read the data curves from. There are four possible responses: one, meaning the Tektronix 4907 File Manager, a disc system; two, the Tektronix 4924 Auxiliary Tape Drive; three, the Tektronix 4051 Internal Tape Drive; and four, meaning the user wants to input data into IGPS by typing it on the keyboard of the 4051.

The user is then prompted for the number of curves he wants to input and for the number of points in the curve having the largest number of points (in other words, for the number  $m_0$  where  $m_0 = \max [m_i, i = 1, \dots, n]$ , where  $n$  is the number of curves being input and  $m_i$  is the number of points in the  $i^{\text{th}}$  curve).

If the user selected the 4907 as the device to use, he is then prompted for the names of the files on which his data reside; if he selected either the 4924 or the internal tape drive, he is then prompted for the numbers of the files; and if he selected the keyboard, he is prompted for the number of points and for the values of the data points in each curve (furthermore, if the user selected y-only data, he is only prompted for the y-axis values, whereas, if he selected x & y data, he is prompted for both x-axis and y-axis values).

When IGPS has read in all the data, it asks for the type of curve marker to be used with each curve. These are nine different curve markers available:

Figure 2.14 Available Curve Markers

Interesting effects can be achieved by plotting the same curve more than once, with a different curve marker each time.

IGPS next prompts for the legend the user wants for each curve; if the user does not want a legend, he should respond with a carriage return. The legend for a particular curve is plotted slightly to the right of the last data point in the curve. This feature was used to create the symbols one through nine in the plot above.

Finally, IGPS prompts for the color the user wants for each curve. Allowable responses are integers between one and eight; these refer to the eight pens in the turret of the Tektronix 4662 x-y plotter equipped with Option 31. The responses are ignored if plotting is either on the screen of the 4051 or on the standard 4662.

If the user selected y-only data, there may now be a slight pause as IGPS sorts the y-axis data and generates the x-axis data. The y-axis data are sorted in place and the original order of the data is therefore lost.

2.4b Output. After the user chooses to output data from IGPS onto a peripheral device, he is prompted for the type of data he wants to save, either y-only or x & y. In the first case, only the y-axis values will be output, whereas in the second, both x-axis and y-axis data are transmitted.

IGPS then prompts for the device the user wishes to output the data to. Possible responses are: one, the 4907; two the 4924; and three, the 4051 Internal Tape. If the user chooses the 4907, IGPS will then ask for the file names on which to write the data; if he chooses the 4924 or the internal tape, it asks for the file numbers.

When writing to the 4907, IGPS will create files of the appropriate size for the data to be written; for tape devices, however, the user must use the MARK command to create the files on his tape before saving data. The tape files must be s bytes long, where

$$s = \begin{cases} 19 + 19 \cdot m & , \quad \text{for y-only data} \\ 19 + 37 \cdot m & , \quad \text{for x \& y data} \end{cases}$$

and m is the number of points in the curve to be written to the file. In practice, the default minimum file size of 768 bytes is adequate for most curves.

If the user attempts to output data without ever having input data during the session, an error message is printed.

2.4c File Structure. Data files to be read by IGPS or written by IGPS are in ASCII format. The structure of an IGPS-compatible file is as follows: (1) the first record in the file contains the number of points in the file; (2) each subsequent record consists of either a single number or of a data pair, depending on whether the file is a y-only or an x & y data file.

2.4d Address Number of the 4924. IGPS assumes that the 4924 Auxiliary Tape Drive is at address 2 of the General Purpose Interface Bus (GPIB). If the user's 4924 is at a different address, he will need to change IGPS. An example will illustrate the required change: if the address wanted is, say, 4 then the user should type in

9350 DO = 4 .

This must be done before initialization of IGPS.

## 2.5 User Key Number 5: Curve Fits.

This key is used to do least-squares, linear fits to the user's data. There are several types of fit available: (1) unconstrained, where IGPS calculates both the slope and intercept of the line which best fits the user's data; (2) fixed-slope, where IGPS calculates the intercept of the best line with user-defined slope; and (3) fixed-intercept, where IGPS calculates the slope of the best line with user-defined intercept. A fourth option allows the user to check the goodness of fit of any line he wishes. In all cases, IGPS operates not on the data the user inputs into IGPS but on the data after it has been transformed via the two functions which define the type of paper the user has asked for (see section 1.3). For instance, if the user asked for xlog paper, the curve fit is to the logarithm of the x-axis data values.

The following equations are used by IGPS for the different curve fits. Assume we are given a set of transformed data  $(x_i, y_i)$ ,  $i = 1, \dots, n$ , where  $n$  is the number of points in the set, to which we wish to fit a line of the form  $y = ax + b$ . The sum of the squares of the vertical deviations between the line and the data points is

$$D = \sum_{i=1}^n [y_i - (ax_i + b)]^2 .$$

In order to do an unconstrained curve fit, in other words, to calculate both  $a$  and  $b$ , we differentiate  $D$  with respect to  $a$  and  $b$  and set the results to zero:

$$\frac{dD}{da} = \sum_{i=1}^n (2) \left[ y_i - (ax_i + b) \right] (-x_i) = 0$$

$$\frac{dD}{db} = \sum_{i=1}^n (2) \left[ y_i - (ax_i + b) \right] (-1) = 0$$

A little algebra reduces these equations to:

$$a = \frac{\sum_{i=1}^n x_i y_i - \sum_{i=1}^n x_i \sum_{i=1}^n y_i}{\sum_{i=1}^n x_i^2 - \left( \sum_{i=1}^n x_i \right)^2}, \text{ and}$$

$$b = \frac{1}{n} \left( \sum_{i=1}^n y_i - a \sum_{i=1}^n x_i \right).$$

In order to do a fixed-slope curve fit, in other words, in order to calculate  $b$  given  $a$ , we differentiate  $D$  with respect to  $b$  and set the result to zero, which yields the equation for  $b$  given above. In order to do a fixed-intercept fit, in other words, in order to calculate  $a$  given  $b$ , we differentiate  $D$  with respect to  $a$  and set the result to zero, which produces:

$$a = \frac{\sum_{i=1}^n x_i y_i - b \sum_{i=1}^n x_i}{\sum_{i=1}^n x_i^2}.$$

In all cases, IGPS calculates and displays a measure of the goodness of fit of the particular line through the data points. The measure is known as  $R^2$  and is defined as:

$$R^2 = 100 \cdot \left\{ 1 - \frac{D}{\sum_{i=1}^n (y_i - \bar{y})^2} \right\},$$

where D is as before and  $\bar{y}$  is the average of  $y_i$ ,  $i=1, \dots, n$ :

$$\bar{y} = \frac{1}{n} \sum_{i=1}^n y_i.$$

From the definition of  $R^2$ , it is apparent that the closer  $R^2$  is to 100, the better the fit.

The prompts associated with user key number 5 are straightforward and require no discussion.

#### 2.6 User Key Number 6: 4051.

This key is used to plot the current graph on the screen of the Tektronix 4051. If the graph is not complete, in other words, if some item of information needed to construct the graph has not been supplied to IGPS, the program will prompt the user for the missing item.

This key is particularly useful in previewing a plot: the user can look at the plot on the screen by depressing this key; if he doesn't like what he sees, he can use the other keys (or the shortcuts described in Section 3) to alter the parameters of the plot; finally, he can depress key number 6 again to quickly see the results of any changes he may have made. Of course, if the user takes no action between depressions of the key, then the plot will be re-drawn on the screen without changes.

Once the user is satisfied with the plot, he can get a copy of it on the Tektronix 4662 x-y plotter by depressing user key number 7.

#### 2.7 User Key Number 7: 4662.

This key is used to obtain a hard copy of the current graph on Tektronix 4662 x-y plotter. Before using this key, the user should prepare the 4662 for plotting by placing a piece of paper in the lower left-hand corner of the plotting area of the 4662. If the piece of paper is 11 inches long and eight and one-half inches high, and if the hardware limits of the 4662 are left at their default values, the plot produced by IGPS will be centered on the piece of paper (see Figure 1.1). To produce plots of different sizes, the user can either change the hardware limits of the 4662 or he can modify the definition of the viewport in IGPS (see the listing of IGPS in Appendix A at lines 6620 through 6660).

IGPS assumes that the 4662 plotter is at address 1 of the GPIB. If the user's 4662 is at a different address, he will need to change line 28 of the program to read

. 28 D=

where the new address goes to the right of the equal sign.

## 2.8 User Key Number 8: Storage and Retrieval.

This key is used to store onto a peripheral or retrieve from a peripheral all the information required to construct a particular plot. This feature is useful in that it allows a complex plot to be saved during one session with IGPS and then quickly reconstructed at a later session without the user having to re-input all the parameters which make up the plot; instead, the entire plot can be recreated by just depressing this one key and responding to a few prompts.

After the user depresses key number 8, IGPS will prompt him for the type of operation to carry out (either storage or retrieval). The user is then prompted for the device he wishes to use. There are three possible responses: one, meaning the 4907 file manager; two, meaning the 4924 Tape Drive; and three, meaning the internal drive. If the user selected the 4907, he is then prompted for the name of the file to use; if he selected the 4924 or the interval tape drive, he is prompted for the number of the file.

If the user attempts to store an incomplete plot, an error message is printed and no further action is taken.

When storing a plot on the 4907, IGPS will create a binary file of the appropriate size for the data to be written; for tape devices, the user must use the MARK command to create the file on his tape. The tape file must be S bytes long, where S is approximately given by the expression

$$S = 1000 + 16 \cdot n \cdot m_0,$$

where n is the number of data curves in the plot and  $m_0$  is the number of points in the curve having the greatest number of points; for instance, storing Figure 1.1 requires approximately 2000 bytes.

The remarks in 2.4d about the address of the 4924 apply here as well.

## 2.9 User Key Number 9: Data Generation.

This key can be used to generate x axis and y axis data from user-defined parametric functions rather than inputting them from a peripheral or the keyboard.

After the user depresses this key, IGPS will prompt with:

DATA TYPE (1=Y ONLY, 2=X&Y):  
NUMBER OF CURVES:  
NUMBER OF POINTS PER CURVE (AT LEAST 2):  
MIN AND MAX OF PARAMETRIC VARIABLE:

The meaning of the DATA TYPE prompt is as before: a response of 1 is a request to IGPS to sort the y axis data in increasing order and to generate x axis data as cumulative fractions.

IGPS will, after the user responds to the prompts, create the data as

$$\begin{aligned} X_{i,j} &= F_x [t_0 + S \cdot (j - 1)] \quad \text{and} \\ Y_{i,j} &= F_y [t_0 + S \cdot (j - 1)] , \end{aligned}$$

where  $j = 1, \dots, m_0$ ,  $i=1, \dots, n$ ,  $n$  and  $m_0$  are the responses to the second and third prompts,

$$S = \frac{t_1 - t_0}{m_0 - 1} ,$$

$t_0$  and  $t_1$  are the minimum and maximum of the parametric variable, and  $F_x$  and  $F_y$  are the user-definable functions. These two functions must be defined by the user before he depresses user key number 9; he must do so by replacing lines 3420 and 3430 in the program with his own functions: line 3420 is for  $F_x$  and must be of the form

3420 DEF FNX(T)=

while line 3430 is for  $F_y$  and must be of the form

3430 DEF FNY(T)=

By default, the definitions are

3420 DEF FNX(T)=RO(I)\*SIN(T)

3430 DEF FNY(T)=RO(I)\*SIN(T)\*COS(T)

where RO is an array with five entries such that

$$RO_i = i, \quad i=1, \dots, 5.$$

Therefore, if the user does not alter the definitions, and if he uses the following sequence

```
DATA TYPE (1=Y ONLY, 2=X&Y):  2
NUMBER OF CURVES:  5
NUMBER OF POINTS PER CURVE:  21
MIN AND MAX OF INDEPENDENT VARIABLE:  0, 6.28
```

then, with appropriate choices of limits, labels, curve types and so on, he should be able to reproduce Figure 2.15.

Figure 2.15 Sample Plot Using Parametric Functions

#### 2.10 User Key Number 10: Menu.

Whenever this key is depressed, IGPS will plot the menu on the screen of the 4051; see Figure 2.1.

Next page is blank

### 3. SHORTCUTS

Suppose you are previewing a plot on the screen of the Tektronix 4051 and you decide to change the type of curve marker being used with one of the curves. One way to do this is to depress user key number 4 and to go through the input procedure; this, however, is clumsy and can be avoided since the variable controlling the type of curve marker is directly available to the user: it is in fact the array LO, with as many entries as there are curves, and with the  $i^{\text{th}}$  entry of LO being an integer between one and nine (see Figure 2.14) corresponding to the type of curve marker to be used with the  $i^{\text{th}}$  curve. Therefore, to change the type of curve marker for a given curve, the user need only change the entry in LO corresponding to that curve. For instance, to draw the third curve as a solid line, the user should type in LO(3)=4.

The same procedure can be used with any of the features of the plot being previewed. To find out the name of the variable which controls the feature of the plot which you want to change, consult Table 3-4.

<u>Name</u>	<u>Type</u>	<u>Description</u>
A0	Simple	Frame type: 0 - None 1 - Axes 2 - Grid 3 - Border
FO	Simple	Color for frame and labels (must be integer between one and eight)
S0	Simple	Pen speed (must be number between 10 and 570)
pa	Simple	Paper type: 1 - linear 2 - Xlog 3 - Ylog 4 - Loglog 5 - User-defined 6 - Uniform probability 7 - Normal probability 8 - Lognormal probability 9 - Rayleigh probability 10 - Weibull probability
N	Simple	Number of curves
MO	Simple	Number of points in the curve with the greatest number
M(N)	Array	M(I) contains the number of points in the $i^{\text{th}}$ curve
X(N,MO) <sup>a</sup>	Array	X(I,J) contains the $j^{\text{th}}$ data point in the $i^{\text{th}}$ curve
Y(N,MO) <sup>a</sup>	Array	Y(I,J) contains the $j^{\text{th}}$ data point in the $i^{\text{th}}$ curve

<sup>a</sup> see remarks

TABLE 3-1 DICTIONARY OF VARIABLES (CONTINUED)

<u>Name</u>	<u>Type</u>	<u>Description</u>
LO(N)	Array	LO(I) contains the curve type for the $i^{\text{th}}$ curve: 1 - Dashed line 2 - Dashed-dotted line 3 - Dotted line 4 - Solid line 5 - Crosses 6 - X-shaped markers 7 - Squares 8 - Triangles 9 - Upside-down triangles
F\$a	String	Legends for the N curves
CO(N)	Array	CO(I) contains the color of the $i^{\text{th}}$ curve and legend (must be integer between one and eight)
C	Simple	Curve fit: 0 - No $\neq 0$ - Yes
A(N) <sup>a</sup>	Array	A(I) contains the slope of the line fit to the $i^{\text{th}}$ set of data
B(N) <sup>a</sup>	Array	B(I) contains the intercept of the line fit to the $i^{\text{th}}$ set of data
R(N) <sup>a</sup>	Array	R(I) contains the $R^2$ - value associated with the fit to the $i^{\text{th}}$ set of data

<sup>a</sup> see remarks

## REMARKS:

1. The strings A\$ and B\$ contain the tick mark labels in compact form, which is to say, A\$ consists of N2 labels juxtaposed and separated by pound signs (#). Therefore, the tick mark labels associated with Figure 2.2 could have been created by typing in

N2=5

A\$="0.00#0.25#0.05#0.75#1.00#"

2. Changes to the variable P must be followed by the statement  
RUN 4410.
3. Unused entries of the arrays X and Y are zero-filled.
4. F\$ contains the N legends in compact form (see remark 1 for a  
definition of compact). The legends in Figure 1.1 could have  
been created by the statement

F\$="MARK I# MARK II#"

5. The contents of the arrays A, B, and R are only meaningful  
if a curve-fit has been performed. Otherwise, they are zero-  
filled.

#### 4. POSTSCRIPT

The author has attempted to make IGPS as useful and versatile as possible and he welcomes recommendations for improving it.
